2 step markov chain I guess

write up explanation of aggregation before vs after, conditional probabilities along with the tree would be a good idea This section is going cover two step clustering based on various clustering methods for comparison. Visit data will be combined into one bee result for each orchard, note in principle this is fundamentally flawed as the data does depend on previous years and the assumption that independent of the past is false as pesticide last year affects bee population this year as would be expected. In these scenarios each implementation will have a maximum of 8 clusters. Two after pre-bloom, 4 after and 8 after post bloom.

```
load("data")
markov_data <- data_2012 %>%
  select(ends_with(".pre"), ends_with(".blm"), ends_with(".pos"), orchard) %>%
  unique()

#Standardising the data for purpose of clustering

markov_data <- markov_data %>%
  mutate(eiqB11F.pre = (eqB11F.pre - mean(eiqB11F.pre))/sd(eiqB11F.pre)) %>%
  mutate(eiqB11I.pre = (eqB11I.pre - mean(eiqB11I.pre))/sd(eiqB11I.pre)) %>%
  mutate(eiqB11F.blm = (eqB11F.blm - mean(eiqB11F.blm))/sd(eiqB11F.blm)) %>%
  mutate(eiqB11I.blm = (eqB11I.blm - mean(eiqB11I.blm))/sd(eiqB11I.blm)) %>%
  mutate(eiqB11T.blm = (eqB11T.blm - mean(eiqB11T.blm))/sd(eiqB11T.blm)) %>%
  mutate(eiqB11F.pos = (eqB11F.pos - mean(eiqB11F.pos))/sd(eiqB11F.pos)) %>%
  mutate(eiqB11I.pos = (eqB11I.pos - mean(eiqB11I.pos))/sd(eiqB11I.pos)) %>%
  mutate(eiqB11T.pos = (eqB11T.pos - mean(eiqB11T.pos))/sd(eiqB11T.pos))

#function to generate the agglomeraative clustering

This demonstrates that to consider the affects on wild bees, just two variables need to be considered as there is very high correlation between the outcomes. WildAbF accounts a .9+ correlation with all wild variables except for the for the solitary bee variable. Then for this SocialRichF could be used.

Updating the bee values to match the environments

In this particular analysis, the interest is in the affects of pesticides on bee population. As such, it is necessary to correct, as best we can, for extra factors (confounding?) to make the bee values representative.

All these graphs were plotted as part of EDA by the use of lapply to the a basic plotting function. Here the relationships between some of the main extra factors (are they confounding?) will be examined.

Temperature

It is known that temperature affects the speed at which bees fly, as such this will have an effect on bee abundance and possibly richness although more bees might not necessarily mean more species are observed. From the previous analysis carried out it is known that a $\log(x) + 1$ transposition of bee count allows for a “better” model fit and as such in general this will the case for our observations.

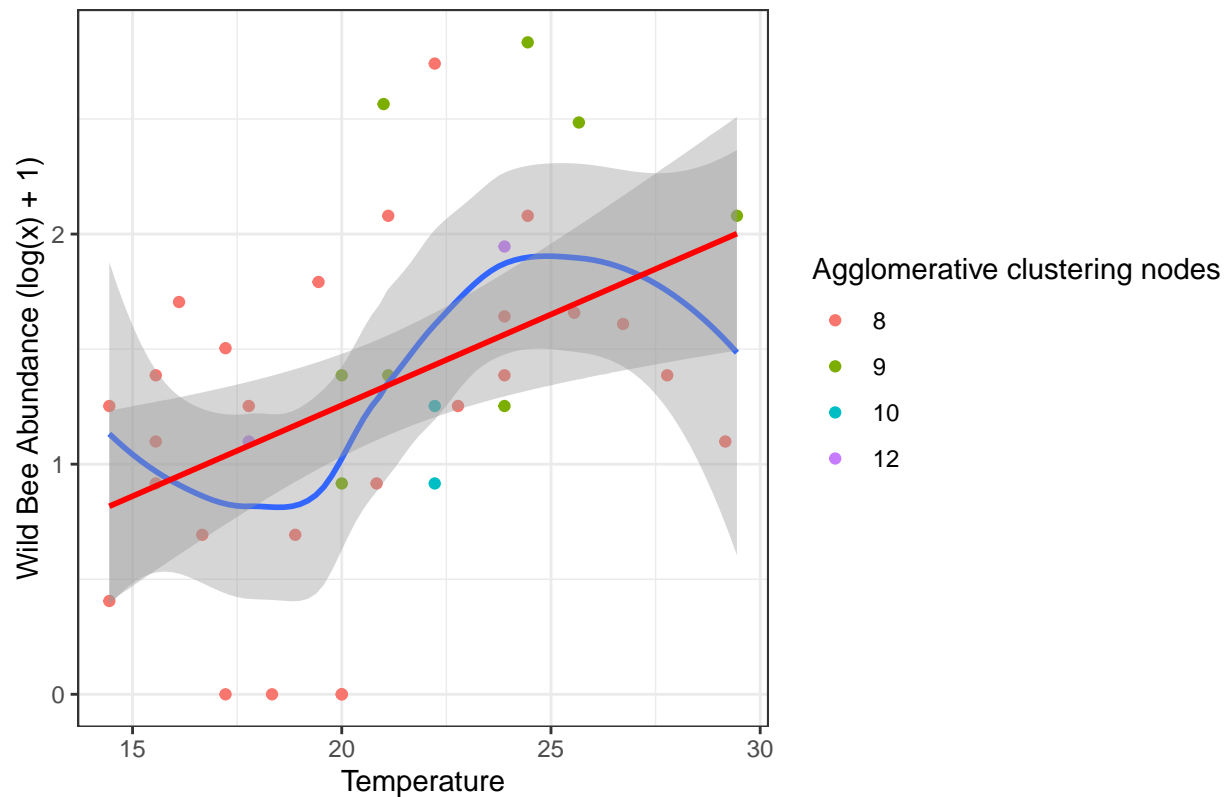

```

Wild Bee Abundance Coloured by Agglomerature Nodes

X2000nat

Based on previous research undertaken in the white paper it is known that the X2000nat variable has an effect on the the bee count so it also necessary to adjust for this. Wher Again the value will be adjust as though the X2000nat variable is constant. In this case the mean will be chosen as the constant value and the bee count will be adjusted for this in the same way as above.

```
wild_bee_abundance_agglom_x2000 <- adjusted_data %>%
  ggplot(aes(x = X2000nat, y = adjusted_beas)) +
  geom_point(aes(colour = as_factor(node))) +
  geom_smooth() +
  geom_smooth(method = "lm", colour = "red") +
  labs(x = "X2000nat", y = "Adjusted Wild Bee Abundance ( $\log(x) + 1$ )",
       title = "Wild Bee Abundance Coloured by Agglomerature Nodes",
       colour = "Agglomerative clustering nodes") +
  theme_bw()
wild_bee_abundance_agglom_x2000
```

```
## `geom_smooth()` using method = 'loess' and formula 'y ~ x'
```

Wild Bee Abundance Coloured by Agglomerative Nodes

```
#Outcome is 0.388
mean_x2000 <- adjusted_data %>%
  summarise(mean_x2000 = mean(X2000nat)) %>%
  as_vector()

lm_X2000nat <- lm(adjusted_data$adjusted_beess ~ adjusted_data$X2000nat)
X2000_factor <- tidy(lm_X2000nat) %>%
  slice(2) %>%
  select(estimate) %>%
  as_vector()

#Adjusting the data for this variable

adjusted_data <- adjusted_data %>%
  mutate(adjusted_beess = ((mean_x2000 - X2000nat) * X2000_factor) + adjusted_beess)
```

So if you look at them individually, it can only be adjusted for one. So need to combine a linear model of all affecting factors to best adjust at the end.

Analysing other potential confounders

This section will look at finding other parameters to include in the bee variable, dataset used at this point is the original just with the bee variable considered going through a $\log(x + 1)$ transformation. The only bee variable to be considered at this point is the wild bee abundance, in future more could be considered in this

way or it would be expected to be similar for all bee variables and I could just use the variables decided upon in this way for all the bee variables considered.

Local Diversity

The aim here is to whether adding local diversity as a adjustment factor is going to be beneficial or not. This will be achieved by running a F test to see whether the variances are equal, a shapiro test to confirm the bee data can be assumed to be normal. Note, independence assumption is not validated, this is due more than 1 result being used from each orchard, I decided to include these as I thought the extra power gained from twice the observations was worth the penalty of this assumption.

```
#When adding temperature in other variables have an effect
logged_data <- data_2012 %>%
  inner_join(clusterings) %>%
  mutate(adjusted_bees = (((20 - temp) * temp_factor) + log(wildAbF + 1)))

## Joining, by = "orchard"

#Just logged
logged_data <- data_2012 %>%
  inner_join(clusterings) %>%
  mutate(adjusted_bees = log(wildAbF + 1))

## Joining, by = "orchard"

#X2000nat adjustment
logged_data <- data_2012 %>%
  inner_join(clusterings) %>%
  mutate(adjusted_bees = log(wildAbF + 1))%>%
  mutate(adjusted_bees = ((mean_x2000 - X2000nat) * X2000_factor) + adjusted_bees)

## Joining, by = "orchard"

#Testing underlying normal data assumption, again demonstrating why the transformation is neccessary:
#Not normal
shapiro.test(logged_data$wildAbF)

##
## Shapiro-Wilk normality test
##
## data: logged_data$wildAbF
## W = 0.79764, p-value = 9.361e-06

#After transformation -> normal

```

Day

Looking at the day to see whether that also has an effect, since the data can be paired by day 1 and day 2 a paired t-test will be carried out on this to test whether there is a difference in bee count. When using just the X2000nat variable, then it becomes very close to significant.

```
day_1 <- logged_data %>% filter(day == 1) %>% select(adjusted_bees) %>% as_vector()
day_2 <- logged_data %>% filter(day == 2) %>% select(adjusted_bees) %>% as_vector()
#This demonstrates that the variances come from the same distribution:
tidy(var.test(day_1, day_2)) %>%
  select(statistic, p.value)
```

```
## Multiple parameters; naming those columns num.df, denom.df
## # A tibble: 1 x 2
##   statistic p.value
##   <dbl>    <dbl>
## 1      0.936    0.891
```

```
#Hence we can run a paired t-test with equal variances
tidy(t.test(adjusted_bees ~ day, logged_data, var.equal = TRUE, paired = TRUE))
```

```
## # A tibble: 1 x 8
##   estimate statistic p.value parameter conf.low conf.high method
##   <dbl>    <dbl>    <dbl>    <dbl>    <dbl>    <dbl> <chr>
## 1   -0.342    -2.02  0.0588        18   -0.697    0.0142 Paire~
## # ... with 1 more variable: alternative <chr>
```

```
#Bit surprising but it demonstrates that there is no statistical significance between days
#So combining values to start with is probably appropriate
```

Bloom

First it shall be graphed to see if there is any obvious correlation.

```
logged_data %>%
  ggplot(aes(x = bloom.index, y = adjusted_bees)) +
  geom_smooth() +
  geom_smooth(method = "lm", colour = "red") +
  theme_bw() +
  geom_point()
```

```
## `geom_smooth()` using method = 'loess' and formula 'y ~ x'
```

There doesn't seem to be any obvious correlation, but just to be sure I'll split the bloom into three categories and test these with an Anova test.

```
logged_data <- logged_data %>%
  mutate(bloom_category = if_else(bloom.index <= 33, 1,
    if_else(bloom.index <= 66, 2, 3)))
```

#Running the anova test

```
anova1 <- aov(adjusted_bees ~ bloom_category, data = logged_data)
summary(anova1)
```

```
##           Df Sum Sq Mean Sq F value Pr(>F)
## bloom_category 1    0.19   0.1897    0.456  0.504
## Residuals    36   14.98   0.4162
```

#As expected there is no evidence to suggest that bloom index (category)

#Has an effect on the bee counts (although only 1 DF in bloom_category thought it should be 2??)

Bloom is a continuous variable but for the sakes of deciding whether to include it or not

Final Confounders

Based on the analysis above, the confounders that could be taken into account are: Region and local diversity based on the statistical tests, temperature and X2000nat based on the literature.

#Checking the variables to see if any are heavily correlated (binary/categorical ones won't be)

#So checking other two and we get a low correlation so acceptable to use them together

```
cor(logged_data$temp, logged_data$X2000nat)
```

```
## [1] 0.2065843
f_lm <- lm(adjusted_beets ~ temp + X2000nat + local.diversity + region, data = logged_data)
#Interesting values here seem to suggest that only significant one is X2000nat
summary(f_lm)

```

Notes, from running the adjustments: When you use temperature as an original adjustment, only significant one in the model is X2000nat and when you use X2000nat in the original data only significant one is temp. When you use neither and just apply the linear model on the logged data then both temp and nat are significant -> suggesting that just these two variables would be best to adjust by. This suggest to me that fitting a joint lm using both temp and X2000nat to adjust the data is probably best to avoid overfitting and keep the model as parsimonious as possible. Despite region and local.diversity being significant for temp adjustment originally, unlikely to be worth implementing but could be considered to cover model changes section. To take this further, could apply lasso regression on the full dataset to see what that comes up with as tends to have a lower MSE than a standard LM.

```
#Using the logged_data with no adjustments
logged_data <- data_2012 %>%
  inner_join(clusterings) %>%
  mutate(adjusted_beets = log(wildAbF + 1)) %>%
  mutate(adjusted_social = log(socialRichF + 1))
```

```
## Joining, by = "orchard"
```

```
#Defining linear model with temp and X2000nat as factors
temp_nat_lm <- tidy(lm(adjusted_beets ~ temp + X2000nat, data = logged_data))
#Extracting temp and nat estimate values
temp_factor <- temp_nat_lm %>%
  select(estimate) %>%
  slice(2) %>%
  as_vector()
nat_factor <- temp_nat_lm %>%
```

```

select(estimate) %>%
slice(3) %>%
as_vector()

#Now adjustments shall be made for these two variables:
#Temperature will be set to 20 degrees
#X2000 nat will be set to the mean x2000 nat value
temp_nat_adjusted <- logged_data %>%
  mutate(adjusted_bees = (adjusted_bees + ((20 - temp) * temp_factor) + ((mean_x2000 - X2000nat) * X2000nat)))

#Checking that after the adjustment they are not significant at all in the model
tidy(lm(adjusted_bees ~ temp + X2000nat, data = temp_nat_adjusted))

```

```

## # A tibble: 3 x 5
##   term          estimate std.error statistic p.value
##   <chr>          <dbl>     <dbl>     <dbl>   <dbl>
## 1 (Intercept)  1.24e+ 0    0.549    2.25e+ 0  0.0309
## 2 temp        -9.42e-18   0.0249  -3.79e-16  1.000
## 3 X2000nat      9.12e- 2    0.735    1.24e- 1  0.902

```

#As expected now the bee abundance has been adjusted for these two parameters

The same process can be applied to the variable SocialRichF, the other bee variable which needs to be considered. Since we know that only temp and nat were statistic on the wildAbF we can go straight to the LM and test that (May need to check this with Julia, if not just cp previous analysis...)

```

#Looking at the model ~ only X2000nat significant

```

```
            mean_social_rich = mean(mean_social_rich))
```

```
##euclidean:
```

```
euclidean_non_markov_clusters <- temp_nat_adjusted %>%
```

```
  group_by(orchard) %>%
```

```
  summarise(mean_honey_ab = mean(apisAb),
```

```
            mean_wild_ab = mean(adjusted_bees),
```

```
            mean_social_rich = mean(adjusted_social)) %>%
```

```
  mutate(cluster = maximum_cluster$cluster) %>%
```

```
  group_by(cluster) %>%
```

```
  summarise(mean_honey_ab = mean(mean_honey_ab),
```

```
            mean_wild_ab = mean(mean_wild_ab),
```

```
            mean_social_rich = mean(mean_social_rich))
```

Although honey bee abundance is one of the summarised variables, this is likely to be related directly to the `hive.acr` variable.

Comparing cluster values before and after adjustments, for now just looking at the agglomerative node clustering selection as it is, in my opinion, better than Kmeans.

```
##agglom
```

```
adjusted_bee_summary$agglom_bees %>%
```

##Just bloom and just fungicide and insecticide

```

Looking at the difference between standardised data and non-standardised data: This section is non-standardised

write up explanation of aggregation before vs after, conditional probabilities along with the tree would be a good idea This section is going cover two step clustering based on various clustering methods for comparison. Visit data will be combined into one bee result for each orchard, note in principle this is fundamentally flawed as the data does depend on previous years and the assumption that independent of the past is false as pesticide last year affects bee population this year as would be expected. In these scenarios each implementation will have a maximum of 8 clusters. Two after pre-bloom, 4 after and 8 after post bloom.

```

load("data")

grid.arrange(p1, p2, nrow = 1)
```

Non-markov structuring

This section will approach looking at the data as one time point with 1 clustering point rather than 3 as above: Method Justification - Maximum linkage function is best for both standardised and unstandardised.

```
maximum_cluster <- data_2012 %>%
  arrange(orchard) %>%
  select(ends_with(".pre"), ends_with(".blm"), ends_with(".pos")) %>%
  filter(row_number() %% 2 == 1)

euclidean_cluster <- maximum_cluster

# matrix of methods to compare,
# rerun - without %>%mutate segment for non-standardised values
m <- c("average", "single", "complete", "ward")
```

```

names(m) <- c("average", "single", "complete", "ward")
distances <- c("euclidean", "maximum", "manhattan", "canberra",
               "minkowski")
names(distances) <- c("euclidean", "maximum", "manhattan",
                     "canberra", "minkowski")
clust_comps <- matrix(nrow = length(distances), ncol = length(m),
                    dimnames = list(distances, m))
# function to compute coefficient to see which is the best method
ac <- function(distance, linkage) {
  dista <- dist(maximum_cluster, method = distance)
  #Agglomerative Nesting form of Hierarchical Clustering
  agnes(dista, method = linkage)$ac
}
for(i in 1:length(distances)) {
  for(j in 1:length(m)) {
    clust_comps[i,j] <- ac(distances[i], m[j])
  }
}

#In future or in write up, perhaps change, needs more clustering analysis
#Look at literature in more detail to see other benefits/drawbacks and assumptions
#Then decide on actual best method, for now using euclidian as used that before
standardised_clust_comps = clust_comps

```

Clustering code - Maximum

```

#NBclust function breaks when using index = all, instead using all the working indexes instead
fviz_nbclust(NbClust(maximum_cluster, distance = "maximum",
                    min.nc = 2, max.nc = 8, method = "ward.D2", index = c("kl", "ch", "ccc")

## Among all indices:
## =====
## * 5 proposed 2 as the best number of clusters
## * 2 proposed 4 as the best number of clusters
## * 3 proposed 7 as the best number of clusters
## * 4 proposed 8 as the best number of clusters
##
## Conclusion
## =====
## * According to the majority rule, the best number of clusters is 2 .

```

Optimal number of clusters – k = 2

```
#Agglomerative clustering
clustered <- agnes(dist(maximum_cluster, method = "maximum"),

            mean_wild_rich = mean(mean_wild_rich))
```

Clustering code - euclidean

*#Clusters of whole data combined - 7 - breaks sometimes with euclidean bit weird but maybe another just
#Euclidean clusters.*

```
fviz_nbclust(NbClust(euclidean_cluster, distance = "euclidean",
                    min.nc = 2, max.nc = 8, method = "ward.D2", index = "all"))
```

```
## *** : The Hubert index is a graphical method of determining the number of clusters.
##       In the plot of Hubert index, we seek a significant knee that corresponds to a
##       significant increase of the value of the measure i.e the significant peak in Hubert
##       index second differences plot.
##
```

```
## *** : The D index is a graphical method of determining the number of clusters.
##           In the plot of D index, we seek a significant knee (the significant peak in Dindex
##           second differences plot) that corresponds to a significant increase of the value of
##           the measure.
##
## *****
## * Among all indices:
## * 2 proposed 2 as the best number of clusters
## * 2 proposed 3 as the best number of clusters
## * 9 proposed 4 as the best number of clusters
## * 2 proposed 5 as the best number of clusters
## * 1 proposed 6 as the best number of clusters
## * 2 proposed 7 as the best number of clusters
## * 5 proposed 8 as the best number of clusters
##
##           ***** Conclusion *****
##
## * According to the majority rule, the best number of clusters is 4
##
## *****
## Among all indices:
## =====
## * 2 proposed 0 as the best number of clusters
## * 1 proposed 1 as the best number of clusters
## * 2 proposed 2 as the best number of clusters
```

```
## * 2 proposed 3 as the best number of clusters
## * 9 proposed 4 as the best number of clusters
## * 2 proposed 5 as the best number of clusters
## * 1 proposed 6 as the best number of clusters
## * 2 proposed 7 as the best number of clusters
## * 5 proposed 8 as the best number of clusters
##
## Conclusion
## =====
## * According to the majority rule, the best number of clusters is 4 .
```

Optimal number of clusters – k = 4

```
#Agglomerative clustering
clustered <- agnes(dist(euclidean_cluster, method = "euclidean"),

This demonstrates that to consider the affects on wild bees, just two variables need to be considered as there is very high correlation between the outcomes. WildAbF accounts a .9+ correlation with all wild variables except for the solitary bee variable. Then for this SocialRichF could be used.

Updating the bee values to match the environments

In this particular analysis, the interest is in the affects of pesticides on bee population. As such, it is necessary to correct, as best we can, for extra factors (confounding?) to make the bee values representative.

All these graphs were plotted as part of EDA by the use of lapply to the a basic plotting function. Here the relationships between some of the main extra factors (are they confounding?) will be examined.

Temperature

It is known that temperature affects the speed at which bees fly, as such this will have an effect on bee abundance and possibly richness although more bees might not necessarily mean more species are observed. From the previous analysis carried out it is known that a $\log(x) + 1$ transposition of bee count allows for a “better” model fit and as such in general this will the case for our observations.

Wild Bee Abundance Coloured by Agglomerature Nodes

X2000nat

Based on previous research undertaken in the white paper it is known that the X2000nat variable has an effect on the the bee count so it also necessary to adjust for this. Wher Again the value will be adjust as though the X2000nat variable is constant. In this case the mean will be chosen as the constant value and the bee count will be adjusted for this in the same way as above.

```
wild_bee_abundance_agglom_x2000 <- adjusted_data %>%
  ggplot(aes(x = X2000nat, y = adjusted_beas)) +
  geom_point(aes(colour = as_factor(node))) +
  geom_smooth() +
  geom_smooth(method = "lm", colour = "red") +
  labs(x = "X2000nat", y = "Adjusted Wild Bee Abundance ( $\log(x) + 1$ )",
       title = "Wild Bee Abundance Coloured by Agglomerature Nodes",
       colour = "Agglomerative clustering nodes") +
  theme_bw()
wild_bee_abundance_agglom_x2000
```

```
## `geom_smooth()` using method = 'loess' and formula 'y ~ x'
```

Wild Bee Abundance Coloured by Agglomerate Nodes

```
#Outcome is 0.388
mean_x2000 <- adjusted_data %>%
  summarise(mean_x2000 = mean(X2000nat)) %>%
  as_vector()

lm_X2000nat <- lm(adjusted_data$adjusted_beas ~ adjusted_data$X2000nat)
X2000_factor <- tidy(lm_X2000nat) %>%
  slice(2) %>%
  select(estimate) %>%
  as_vector()

#Adjusting the data for this variable

adjusted_data <- adjusted_data %>%
  mutate(adjusted_beas = ((mean_x2000 - X2000nat) * X2000_factor) + adjusted_beas)
```

So if you look at them individually, it can only be adjusted for one. So need to combine a linear model of all affecting factors to best adjust at the end.

Analysing other potential confounders

This section will look at finding other parameters to include in the bee variable, dataset used at this point is the original just with the bee variable considered going through a $\log(x + 1)$ transformation. The only bee variable to be considered at this point is the wild bee abundance, in future more could be considered in this

way or it would be expected to be similar for all bee variables and I could just use the variables decided upon in this way for all the bee variables considered.

Local Diversity

The aim here is to whether adding local diversity as a adjustment factor is going to be beneficial or not. This will be achieved by running a F test to see whether the variances are equal, a shapiro test to confirm the bee data can be assumed to be normal. Note, independence assumption is not validated, this is due more than 1 result being used from each orchard, I decided to include these as I thought the extra power gained from twice the observations was worth the penalty of this assumption.

```
#When adding temperature in other variables have an effect
logged_data <- data_2012 %>%
  inner_join(clusterings) %>%
  mutate(adjusted_bees = (((20 - temp) * temp_factor) + log(wildAbF + 1)))

## Joining, by = "orchard"

## 1      1.22      1.41    -0.896  0.376        36    -0.617      0.239 " Two~
## # ... with 1 more variable: alternative <chr>
```

From This analysis, it can be concluded that local.diversity does NOT play a factor in bee count ### Region Region has 3 possible options - as such an ANOVA test will be used to see whether there is a difference between the means in wild abundance based on region.

```
#Checking Anova assumption that the variances are the same
# H0: Variances the same: H1: Atleast one variance is different
leveneTest(adjusted_beas ~ region, data = logged_data)
```

```
## Levene's Test for Homogeneity of Variance (center = median)
##      Df F value Pr(>F)
## group 2  0.1954 0.8234
##      35
```

```
#Since pr > 0.05 we can assume variances are the same
```

```
#Running the anova test
anova1 <- aov(adjusted_beas ~ region, data = logged_data)

summary(anova1)
```

```
##      Df Sum Sq Mean Sq F value Pr(>F)
## region 2  0.522  0.2611  0.624  0.542
## Residuals 35 14.652  0.4186
```

```
#probability shows that region is not an affecting factor to wildAbF
```

```
#Checking that the following anova assumption is TRUE:
#Residuals of the response variable are normally distributed is NOT true
shapiro.test(residuals(anova1))
```

```
##
## Shapiro-Wilk normality test
##
## data: residuals(anova1)
## W = 0.96856, p-value = 0.3546
```

Day

Looking at the day to see whether that also has an effect, since the data can be paired by day 1 and day 2 a paired t-test will be carried out on this to test whether there is a difference in bee count. When using just the X2000nat variable, then it becomes very close to significant.

```
day_1 <- logged_data %>% filter(day == 1) %>% select(adjusted_bees) %>% as_vector()
day_2 <- logged_data %>% filter(day == 2) %>% select(adjusted_bees) %>% as_vector()
#This demonstrates that the variances come from the same distribution:
tidy(var.test(day_1, day_2)) %>%
  select(statistic, p.value)
```

```
## Multiple parameters; naming those columns num.df, denom.df
## # A tibble: 1 x 2
##   statistic p.value
##   <dbl>    <dbl>
## 1      0.936    0.891
```

```
#Hence we can run a paired t-test with equal variances
tidy(t.test(adjusted_bees ~ day, logged_data, var.equal = TRUE, paired = TRUE))
```

```
## # A tibble: 1 x 8
##   estimate statistic p.value parameter conf.low conf.high method
##   <dbl>    <dbl>    <dbl>    <dbl>    <dbl>    <dbl> <chr>
## 1   -0.342    -2.02  0.0588        18   -0.697    0.0142 Paire~
## # ... with 1 more variable: alternative <chr>
```

```
#Bit surprising but it demonstrates that there is no statistical significance between days
#So combining values to start with is probably appropriate
```

Bloom

First it shall be graphed to see if there is any obvious correlation.

```
logged_data %>%
  ggplot(aes(x = bloom.index, y = adjusted_bees)) +
  geom_smooth() +
  geom_smooth(method = "lm", colour = "red") +
  theme_bw() +
  geom_point()
```

```
## `geom_smooth()` using method = 'loess' and formula 'y ~ x'
```

There doesn't seem to be any obvious correlation, but just to be sure I'll split the bloom into three categories and test these with an Anova test.

```
logged_data <- logged_data %>%
  mutate(bloom_category = if_else(bloom.index <= 33, 1,
    if_else(bloom.index <= 66, 2, 3)))
```

#Running the anova test

```
anova1 <- aov(adjusted_bees ~ bloom_category, data = logged_data)
summary(anova1)
```

```
##           Df Sum Sq Mean Sq F value Pr(>F)
## bloom_category 1    0.19   0.1897    0.456  0.504
## Residuals    36   14.98   0.4162
```

#As expected there is no evidence to suggest that bloom index (category)

#Has an effect on the bee counts (although only 1 DF in bloom_category thought it should be 2??)

Bloom is a continuous variable but for the sakes of deciding whether to include it or not

Final Confounders

Based on the analysis above, the confounders that could be taken into account are: Region and local diversity based on the statistical tests, temperature and X2000nat based on the literature.

#Checking the variables to see if any are heavily correlated (binary/categorical ones won't be)

#So checking other two and we get a low correlation so acceptable to use them together

```
cor(logged_data$temp, logged_data$X2000nat)
```

```
## [1] 0.2065843

```

Notes, from running the adjustments: When you use temperature as an original adjustment, only significant one in the model is X2000nat and when you use X2000nat in the original data only significant one is temp. When you use neither and just apply the linear model on the logged data then both temp and nat are significant -> suggesting that just these two variables would be best to adjust by. This suggest to me that fitting a joint lm using both temp and X2000nat to adjust the data is probably best to avoid overfitting and keep the model as parsimonious as possible. Despite region and local.diversity being significant for temp adjustment originally, unlikely to be worth implementing but could be considered to cover model changes section. To take this further, could apply lasso regression on the full dataset to see what that comes up with as tends to have a lower MSE than a standard LM.

```
#Using the logged_data with no adjustments
logged_data <- data_2012 %>%
  inner_join(clusterings) %>%
  mutate(adjusted_beets = log(wildAbF + 1)) %>%
  mutate(adjusted_social = log(socialRichF + 1))
```

```
## Joining, by = "orchard"
```

```
#Defining linear model with temp and X2000nat as factors
temp_nat_lm <- tidy(lm(adjusted_beets ~ temp + X2000nat, data = logged_data))
#Extracting temp and nat estimate values
temp_factor <- temp_nat_lm %>%
  select(estimate) %>%
  slice(2) %>%
  as_vector()
nat_factor <- temp_nat_lm %>%
```

```

select(estimate) %>%
slice(3) %>%
as_vector()

#Now adjustments shall be made for these two variables:
#Temperature will be set to 20 degrees
#X2000 nat will be set to the meean x2000 nat value
temp_nat_adjusted <- logged_data %>%
  mutate(adjusted_bees = (adjusted_bees + ((20 - temp) * temp_factor) + ((mean_x2000 - X2000nat) * X2000nat))

#Checking that after the adjustment they are not significant at all in the model
tidy(lm(adjusted_bees ~ temp + X2000nat, data = temp_nat_adjusted))

```

```

## # A tibble: 3 x 5
##   term          estimate std.error statistic p.value
##   <chr>          <dbl>    <dbl>    <dbl>   <dbl>

Clustering Summarising

Functions involved with summarising the clusters:

```

#Gets the name of a variable as a string ~ now implemented in clusterise but keeping
get_name <- function(x) {
  deparse(substitute(x))
}

#Gets the bee variables that I am summarising for each cluster - makes it easy to change in future
clusterise <- function(bee_data, cluster_data, v_name = deparse(substitute(cluster_data))){
  inner_join(bee_data, cluster_data) %>%
    summarise(mean_honey_ab = mean(mean_honey_ab),
              mean_wild_ab = mean(mean_wild_ab),
              mean_social_rich = mean(mean_social_rich)) %>%
    mutate(cluster = v_name)
}

#The function to output the summaries of both agglom and kmeans clustering
cluster_summarise <- function(bee_data){
  output <- list()

  output$agglom_beas <- clusterise(bee_data, aggl_node1) %>%
    bind_rows(clusterise(bee_data, aggl_node2)) %>%
    bind_rows(clusterise(bee_data, aggl_node3)) %>%
    bind_rows(clusterise(bee_data, aggl_node4)) %>%
    bind_rows(clusterise(bee_data, aggl_node5)) %>%
    bind_rows(clusterise(bee_data, aggl_node6)) %>%
    bind_rows(clusterise(bee_data, aggl_node7)) %>%

            mean_wild_ab = mean(mean_wild_ab),
```

```
            mean_social_rich = mean(mean_social_rich))
```

Although honey bee abundance is one of the summarised variables, this is likely to be related directly to the `hive.acr` variable.

Comparing cluster values before and after adjustments, for now just looking at the agglomerative node clustering selection as it is, in my opinion, better than Kmeans.

```

```

I guess potentially can see two *paths* one with a mean slightly lower than the other if you think of the structure.

Looking at clusters

The aim of this section is to look at the clusterings from a low, medium, high point of view...

```

#Non_markov clustering summary maximum
maximum_final <- maximum_cluster %>%
  group_by(cluster) %>%
  summarise_all(funs(mean)) %>%
  inner_join(maximum_non_markov_clusters)
